SEARCH REQUEST FORM

Scientific and Technical Information Center

Requester's Full Name: Jennifer Kim Examiner # : 77469 Date: 7/1/03
Art Unit: 1617 Phone Number 30 8-2232 Serial Number: 09/719770
Mail Box and Bldg/Room Location: 2D17 Results Format Preferred (circle): PAPER DISK E-MAIL
2B19

If more than one search is submitted, please prioritize searches in order of need. MEJ

****

Please provide a detailed statement of the search topic, and describe as specifically as possible the subject matter to be searched. Include the elected species or structures, keywords, synonyms, acronyms, and registry numbers, and combine with the concept or utility of the invention. Define any terms that may have a special meaning. Give examples or relevant citations, authors, etc, if known. Please attach a copy of the cover sheet, pertinent claims, and abstract.

Title of Invention: Methods + Compositions for treating diseases mediated by transglutaminase activity

Inventors (please provide full names): Laurence Steinman

Earliest Priority Filing Date: 6/17/98

**For Sequence Searches Only* Please include all pertinent information (parent, child, divisional, or issued patent numbers) along with the appropriate serial number.*

1) Please search claims 1-3, 15+16 based on the disease listed in claim 3 with active agent of claim 8 & 7 Monodansyl cadaverine!!

2) Please provide registry # of ↑

THX,

Mary Hale, Information Branch Supervisor
308-4258, CM1-1E01

Voluntary Results Feedback Form

- *I am an examiner in Workgroup:* ☐ *Example: 1610*
- *Relevant prior art **found**, search results used as follows:*
  - ☐ 102 rejection
  - ☐ 103 rejection
  - ☐ Cited as being of interest.
  - ☐ Helped examiner better understand the invention.
  - ☐ Helped examiner better understand the state of the art in their technology.

  Types of relevant prior art found:
  - ☐ Foreign Patent(s)
  - ☐ Non-Patent Literature
    (journal articles, conference proceedings, new product announcements etc.)
- *Relevant prior art **not found:***
  - ☐ Results verified the lack of relevant prior art (helped determine patentability).
  - ☐ Results were not useful in determining patentability or understanding the invention.

CC 1-11 (Pharmacology)
AB An expanded polyglutamine domain in huntingtin underlies the pathogenic events in **Huntington** disease (HD), characterized by **chorea**, dementia and severe wt. loss, culminating in death. **Transglutaminase** (TGase) may be crit. in the pathogenesis, via crosslinking huntingtin. Administration of the TGase competitive inhibitor cystamine to transgenic mice expressing exon 1 of huntingtin contg. an expanded polyglutamine repeat, altered the course of their HD-like disease. Cystamine given i.p. entered the brain, where it inhibited TGase activity. When treatment was begun after the appearance of abnormal movements, cystamine extended survival, reduced the assocd. tremor and abnormal movements and ameliorated wt. loss. Treatment did not influence the appearance or frequency of neuronal nuclear inclusions. Unexpectedly, cystamine increased transcription of one of the two genes shown to be neuroprotective for polyglutamine toxicity in Drosophila, dnaj (also known as HD/1 and Hsp40 in humans and mice, resp.). Inhibition of TGase provides a new treatment strategy for HD and other polyglutamine diseases.

AB To investigate possible biochem. mechanisms underlying the "toxic gain of function" assocd. with polyglutamine expansions, the ability of guinea pig liver tissue **transglutaminase** to catalyze covalent attachments of various polyamines to polyglutamine peptides was examd. Of the polyamines tested, spermine is the most active substrate, followed by spermidine and putrescine. Formation of covalent crosslinks between polyglutamine peptides and polyamines yields high-Mr aggregates - a process that is favored with longer polyglutamines. In the presence of tissue **transglutaminase**, purified glyceraldehyde-3-phosphate dehydrogenase (a key glycolytic enzyme that binds tightly to the polyglutamine domains of both huntingtin and **dentatorubral-pallidoluysian atrophy** proteins) is covalently attached to polyglutamine peptides in vitro, resulting in the formation of high-Mr aggregates. In addn., endogenous glyceraldehyde-3-phosphate dehydrogenase of a Balb-c 3T3 fibroblast cell line overexpressing human tissue **transglutaminase** forms crosslinks with a Q60 polypeptide added to the cell homogenate. Possibly, expansion of polyglutamine domains (thus far known to occur in the gene products assocd. with at least seven neurodegenerative diseases) leads to increased/aberrant tissue **transglutaminase**-catalyzed crosslinking reactions with both polyamines and susceptible proteins, such as glyceraldehyde-3-phosphate dehydrogenase. Formation of crosslinked heteropolymers may lead to deposition of high-Mr protein aggregates, thereby contributing to cell death.

AB Different proteins bearing polyglutamine of excessive length are lethal to neurons and cause human disease of the central nervous system. In parts of the brain affected by **Huntington**'s disease, the amt. of the huntingtin with expanded polyglutamine is reduced and there appear huntingtin-contg. polymers of larger mol. wt. We show here that huntingtin is a substrate of **transglutaminase** in vitro and that the rate const. of the reaction increases with length of the polyglutamine over a range of an order of magnitude. As a result, huntingtin with expanded polyglutamine is preferentially incorporated into polymers. Both disappearance of the huntingtin with expanded polyglutamine and its replacement by polymeric forms are prevented by inhibitors of **transglutaminase**. The effect of **transglutaminase** therefore duplicates the changes in the affected parts of the brain.

AB To elucidate the mol. mechanisms whereby expanded polyglutamine stretches elicit a grain of toxic function, we expressed full-length and truncated DRPLA (**dentatorubral-pallidoluysian atrophy**)

cDNAs with or without expanded CAG repeats in COS-7 cells. We found that truncated DRPLA proteins contg. an expanded polyglutamine stretch form filamentous peri- and intranuclear aggregates and undergo apoptosis. The apoptotic cell death was partially suppressed by the **transglutaminase** inhibitors cystamine and **monodansyl cadaverine** (but not putrescine), suggesting involvement of a **transglutaminase** reaction and providing a potential basis for the development of therapeutic measures for CAG-repeat expansion diseases.

AB Several adult-onset neurodegenerative diseases are caused by genes with expanded CAG triplet repeats within their coding regions and extended polyglutamine (Qn) domains within the expressed proteins. Generally, in clin. affected individuals n .gtoreq. 40. Glyceraldehyde 3-phosphate dehydrogenase binds tightly to four Qn disease proteins, but the significance of this interaction is unknown. The authors now report that purified glyceraldehyde 3-phosphate dehydrogenase is inactivated by tissue **transglutaminase** in the presence of glutathione S-transferase constructs contg. a Qn domain of pathol. length (n = 62 or 81). The dehydrogenase is less strongly inhibited by tissue **transglutaminase** in the presence of constructs contg. shorter Qn domains (n = 0 or 10). Purified .alpha.-ketoglutarate dehydrogenase complex also is inactivated by tissue **transglutaminase** plus glutathione S-transferase constructs contg. pathol.-length Qn domains (n = 62 or 81). Apparently, tissue **transglutaminase**-catalyzed covalent linkages involving the larger poly-Q domains may disrupt cerebral energy metab. in CAG/Qn expansion diseases.

AB Huntington's disease and six other neurodegenerative diseases are assocd. with abnormal gene products contg. expanded polyglutamine (poly-Q; Qn) domains (n .gtoreq. 40). In the present work, the authors show that glutathione S-transferase (GST) fusion proteins contg. a small, physiol.-length poly-Q domain (GSTQ10) or a large, pathol.-length poly-Q domain (GSTQ62) are excellent substrates of guinea pig liver (tissue) **transglutaminase** and that both GSTQ10 and GSTQ62 are activators of tissue **transglutaminase**-catalyzed hydroxaminolysis of N-.alpha.-carbobenzoxyglutaminylglycine. The present findings have implications for understanding the pathophysiol. mechanisms of expanded CAG/poly-Q domain diseases.

AB Many proteins contain reiterated glutamine residues, but polyglutamine of excessive length may result in human disease by conferring new properties on the protein contg. it. One established property of a glutamine residue, depending on the nature of the flanking residues, is its ability to act as an amine acceptor in a **transglutaminase**-catalyzed reaction and to make a glutamyl-lysine cross-link with a neighboring polypeptide. To learn whether glutamine repeats can act as amine acceptors, we have made peptides with variable lengths of polyglutamine flanked by the adjacent amino acid residues in the proteins assocd. with spinocerebellar ataxia type 1 (SCA1), Machado-Joseph disease (SCA3), or dentato-rubral pallidoluysian atrophy (DRPLA) or those residues adjacent to the preferred crosslinking site of involucrin, or solely by arginine residues. The polyglutamine was found to confer excellent substrate properties on any sol. peptide; under optimal conditions, virtually all the glutamine residues acted as amine acceptors in the reaction with glycine ethyl-ester, and lengthening the sequence of polyglutamine increased the reactivity of each glutamine residue. In the presence of **transglutaminase**, peptides contg. polyglutamine formed insol. aggregates with the proteins of brain exts. and these aggregates contained glutamyl-lysine cross-links. Repeated glutamine residues exposed on the surface of a neuronal protein should form cross-linked aggregates in the presence of any **transglutaminase** activated by the presence of Ca2+.

AB To elucidate the molecular mechanisms whereby expanded polyglutamine stretches elicit a gain of toxic function, we expressed full-length and truncated DRPLA (**dentatorubral-pallidoluysian atrophy**) cDNAs with or without expanded **CAG** repeats in COS-7 cells. We found that truncated DRPLA proteins containing an expanded polyglutamine stretch form filamentous peri- and intranuclear aggregates and undergo apoptosis. The apoptotic cell death was partially suppressed by the **transglutaminase** inhibitors cystamine and **monodansyl cadaverine** (but not putrescine), suggesting involvement of a **transglutaminase** reaction and providing a potential basis for the development of therapeutic measures for **CAG**-repeat expansion diseases.

DT Article
LA English
AB The brain of Alzheimer's disease (AD) patients contains deposits of amyloid beta-peptide (A-beta). Recent studies have shown that A-beta is a substrate for tissue **transglutaminase** (TGase), which induces the

formation of cross-linked dimers and polymers, and that tacrine, indomethacin and deferoxamine, which have widely different chemical structures, attenuate the progression of symptoms of AD. This report evaluated the potential of a total of ten different pharmacological agents to inhibit TGase-induced cross-linking of A-beta, including known TGase inhibitors (**dansylcadaverine**, spermine), non-steroidal anti-inflammatory drugs (indomethacin, meclofenamic acid, diflunisal, salicylic acid), monoamine oxidase inhibitors (tranylcypromine, phenelzine), an acetylcholinesterase inhibitor (tacrine), and an iron chelating agent (deferoxamine). All but one (salicylic acid) of these ten agents had an inhibitory effect on TGase-induced A-beta cross-linking. These results suggest that inhibition of TGase-induced cross-linking of A-beta is a potential pharmacologic target for the treatment of AD. A method is also presented for the determination of percent inhibition of TGase-induced A-beta cross-linking based on the separated monomer, dimer and polymer bands on SDS-PAGE gels.

h
is toxin (TeTX) has been demonstrated to inhibit transmitter release
o mechanisms: Zn-2+dependent proteolytic cleavage of synaptobrevin

and activation of a neuronal **transglutaminase**. Herein, attenuation of TeTX-induced blockade of noradrenaline release from synaptosomes was achieved by prior disassembly of microfilaments with cytochalasin D or breakdown of microtubules by colchicine or nocodazole. These drugs and **monodansylcadaverine**, a **transglutaminase** inhibitor, displayed some additivity in antagonizing the inhibitory effect of the toxin on synaptosomal transmitter release; as none of them reduced synaptobrevin cleavage, all appear to work independently of the toxin's proteolytic action. Prior stabilization of microtubules with taxol prevented the antagonism seen with colchicine, highlighting that this cytoskeletal component is the locus of the effect of colchicine. Replacement of Ca-2+ with Ba-2+ caused disappearance of the fraction of evoked secretion whose inhibition by TeTX is reliant on polymerized actin but did not alter the blockade by toxin that is dependent on microtubules. Two temporally distinguished phases of release were reduced by TeTX, and colchicine lessened its effects on both. Blockade of the fast phase (ltoreq 10 s) of secretion by TeTX was unaffected by cytochalasin D, but it clearly antagonized the toxin-induced inhibition of the slow (10-s to gtoreq 5-min) component; it is notable that such antagonism was accentuated during a second bout of evoked release. These findings are consistent with sustained release requiring dissociation of synaptic vesicles from the microfilaments, a step that seems to be perturbed by TeTX.

DT Article

LA English
AB It has been suggested that the Ca-2+-dependent enzyme **transglutaminase** (TGase) may suppress vesicular neurotransmitter release and mediate the inhibitory effect of tetanus toxin (TetTx) on exocytosis. The aim of the present study was to test this in a model of (3H)5-HT release from superfused rat cortical synaptosomes. **Monodansylcadaverine**, a synthetic amine chat acts as an alternative substrate for TGase, showed dose-dependent releasing activity which, however, was Ca-2+-independent, being maintained in a Ca-2+-free buffer (containing EGTA) or using synaptosomes preloaded with the intracellular Ca-2+ chelator BAPTA. Preincubation of synaptosomes with RS-48373, an irreversible TGase inactivator, resulted in marked (64%) and persistent inhibition of endogenous TGase but did not alter basal and K+-induced (3H)5-HT release. Preincubation of synaptosomes with 10 nM TetTx resulted in 52% inhibition of K+-induced (3H)5-HT release, and this effect was not antagonized in RS-48373-treated synaptosomes. The inhibitory effect of TetTx was significantly antagonized by 20 mM captopril, a metalloendoprotease inhibitor, confirming in rat brain synaptosomes that TetTx inhibits exocytosis by acting as a metalloendoprotease. These results suggest that TGase is not involved in controlling (3H)5-HT release from resting and depolarized synaptosomes, or in the inhibitory effect of TetTx.

AB The effects of **dansylcadaverine** and methylamine, competitive inhibitors of **transglutaminase**, were examined in primary cultures of dissociated rat cerebellar neurons. Addition of the drugs at plating time resulted 24 hr later in irreversible cytotoxic effects evidenced by failure of aggregation and neurite formation. Cytotoxicity was dose-dependent with methylamine being more potent (IC50 = 20 .mu.M) than **dansylcadaverine** (IC50 = 30 .mu.M). The cytotoxic effects were less potent when drugs were added 24 hr after plating, the time when neurons had already begun to extend neurites. Drugs were effective in the various sera and heat-inactivated sera tested. We concluded that low doses of methylamine and **dansylcadaverine** have potent toxic effects on primary neuronal cultures.

AB The accumulation in aged human neurons of insoluble, high-MW filamentous polymers apparently linked by nondisulfide covalent bonds led to the examination of human brain for the presence of **transglutaminase** (EC 2.3.2.13) and endogenous protein substrates for this crosslinking enzyme. The presence of a transamidating enzyme that can covalently crosslink brain proteins into insoluble polymers in vitro by forming .gamma.-glutamyl-.epsilon.-lysine intermolecular bridges was demonstrated. Brain **transglutaminase** is Ca2+ dependent, has an electrophoretic mobility similar to that of erythrocyte **transglutaminase** and is active in human postmortem brain from aged normal individuals and patients with Alzheimer disease (senile dementia). Brain neurofilament fractions incubated in the presence of **transglutaminase**, Ca2+ and the fluorescent amine **dansylcadaverine** form a fluorescent, nondisulfide-bonded insoluble polymer; this process is associated with a decrease in the amount of soluble neurofilament polypeptides in the preparation. EM of the polymeric material reveals an extensive network of connecting filaments, which can be immunostained with various neurofilament antisera. Cystamine, an inhibitor of **transglutaminase**, prevents the neurofilament crosslinking. Glial

filaments and myelin basic protein can also serve as substrates of brain **transglutaminase** in vitro. Although Alzheimer disease-type paired helical filaments were not formed under the specific in vitro coinditions employed, the data suggest 1 possible mechanism for the covalent crosslinking of filaments into insoluble polymers during human neuronal aging.

NOVELTY - Treatment of **transglutaminase** (T) mediated diseases involves administration of its inhibitor (TI).

ACTIVITY - Nootropic; antirheumatic; neuroprotective; antidiabetic; antiinflammatory. The antiinflammatory activity of a (TI), **monodansyl cadaverine** was tested using paraparetic mice with experimental autoimmune encephalomyelitis induced by injecting 4 mg of mouse spinal cord homogenate. 0.05 mM **monodansyl cadaverine** was injected intraperitoneally into one of two groups of mice after 13 days of disease induction. A significant influence (p=0.03 compared to control) of this inhibitor occured after the second day of injection and mice treated with the **monodansyl cadaverine** showed reversal in the paralytic disease.

MECHANISM OF ACTION - **Transglutaminase** inhibitor.

USE - The composition comprising (TI) is used in the treatment of (TI) mediated diseases like neurodegenerative diseases caused by aggregation of polyQ proteins, Huntington's disease, spinobulbar atrophy, spinocerebellar ataxia, dentatorubralpallidoluysian atrophy, cell mediated autoimmune disease like rheumatoid arthritis, multiple sclerosis or insulin dependent diabetes mellitus and other inflammatory diseases of the central nervous system (claimed).

ADVANTAGE - None given.

TECH UPTX: 20000313

TECHNOLOGY FOCUS - BIOTECHNOLOGY - Preferred Method: (TI) can also be presented as an antisense DNA of (T) gene or as DNA encoding it and is introduced into the cell of patient. The method of DNA introduction includes receptor mediated gene delivery, transkaryotic implantation, viral shuttle vectors, direct injection of non-infectious, non-oncogenic plasma DNA encapsulated in liposomes, immunoliposomes and a liposome/red blood cell membrane hybrid.

ABEX UPTX: 20000313

SPECIFIC COMPOUNDS - The specific (TI) compounds are **monodansyl cadaverine**, cystamine, putrescine, gamma-amino benzoic acid, N-benzyloxy carbonyl, 5-deazo-4-oxonorvaline p-nitrophenylester, glycine methyl ester, CuSO4, and tolbutamide (claimed).

ADMINISTRATION - Administration can be by any preferred route e.g. intraperitoneal, subcutaneous, oral routes and are given in dosages of 0.0001-100 mg/kg body weight daily.

AB WO 9804245 A UPAB: 19980323
Use of an inhibitor of **transglutaminase** in promoting healing of wounds or fibrotic disorders with reduced scarring.
Also claimed is the use of a stimulator of **transglutaminase** activity in promoting healing of chronic wounds.
The **transglutaminase** is type II **transglutaminase**.
The inhibitor is an active site inhibitor or is a substrate competitive inhibitor. It is selected from cystamine, **monodansyl cadaverine**, 2-(3-(diallylamino) propionyl) benzothiophene, putrescine, bacitracin, a neutralising antibody (or an antigen-binding fragment of this specific to **transglutaminase**) or a derivative of 2((2-oxopropyl)thio) imidazolium. The neutralising antibody is an IgG antibody specific to **transglutaminase** and is a monoclonal antibody, polyclonal antibody or genetically engineered antibody.
USE - The **transglutaminase** inhibitor is used for promoting healing of wounds (e.g. skin wounds, tendon damage, crush injuries, eye wounds, central nervous system injuries or scar tissue formation resulting from strokes) or fibrotic disorders (e.g. pulmonary fibrosis, glomerulonephritis, liver cirrhosis or proliferative vitreo retinopathy). The **transglutaminase** stimulator may be used in treatment of chronic wounds (e.g. venous ulcers, diabetic ulcers or bed sores).
ADVANTAGE - The inhibitor/stimulator reduce scarring. Scar tissue formation provides mechanical strength to healed wounds but can be unsightly and may impair the function of the tissue. This is especially the case in the central nervous system.

The **transglutaminase** inhibitor is e.g. **monodansyl**

cadaverine (MDC), which may be used to arrest the growth of B lymphocytes, T lymphocytes or monocytes (in a cell cycle G1-phase). Another cpd. 1-(5-aminopentyl)-3-phenylthiourea (PPTU), is claimed for arresting B lymphocyte growth.

The inhibitors arrest the growth of normal and neoplastic B and T lymphocytes, preventing their entry into the S-phase of the cell cycle. The in vitro activity of MDC and PPTU indicate that these cpds. would be highly desirable adjunct to chemotherapy.
